My approach on successfully creating a basic API with flask application.
Description of application design :

- The goal is to create an application programming interface so the user is able to pull and push data to a specific dictionary.
- I have imported Jsonify from the Flask Library.
- I have created multiple routes for the user, such as Homepage, Dictionary content, specific course details
- The besic route is the server's homepage.
- There will be a route where users can request the output of the dictionary.
- There will be a route where users can call a specific cours from the dictionary and add the new course to the dictionary.
